ARTICLE

Will The Internet Of 2027 Still Be Free? Cyberattacks Could Change Everything

BY PNW STAFF OCTOBER 31, 2026

Share this article:

Share Post Email Share Print

Imagine opening your banking app in 2027. Before you can see your balance, it asks for a face scan. A news site wants verified identification before letting you comment. An AI security system flags your activity as suspicious and blocks your account until you prove you are really you.

Task and time tracking

time tracking and billing for freelancers and small teams.

todo.vu

That future is not inevitable. But as cyberattacks grow more disruptive, governments and technology companies will face mounting pressure to make the internet safer. The question is what "safer" will mean--and whether the protections introduced after a crisis will also bring more tracking, identity checks and control.

The internet we know today could look very different by 2027.

The attacks are already crossing borders

This week, Binance reported a major breach involving billions of dollars in digital assets, while Polymarket suspended trading after a third-party security incident caused losses for some users. The threat is not confined to crypto platforms.

In South Korea, breaches affecting several major banks prompted an emergency response from financial authorities; investigators and security researchers have examined evidence that attackers used AI tools. In France, a cyberattack disrupted refrigeration systems at roughly 700 supermarkets, spoiling food and raising concerns about the food supply. These are just some of the more recent attacks but they have been steadily increasing all year.

These incidents show how cyberattacks can reach financial networks and physical systems across the world. AI can help attackers sort through information, identify weaknesses, write code and scale up familiar tactics. That does not mean machines are independently launching every attack. It means people with malicious intent may be able to do more, faster.

The targets extend well beyond banks and exchanges. Cities rely on connected systems to run services. Hospitals depend on digital networks to coordinate care. Water utilities use computer systems to monitor and control equipment. Government agencies, power providers and food distribution networks are all exposed to disruption.

Federal authorities have warned about attacks on water and wastewater systems, including incidents that interfered with monitoring or control. A breach at a financial site can be devastating. An attack that disrupts water, hospital services or city operations could affect thousands of people who have no idea how the intrusion began.

Prophecy News Watch has been attacked several times this week, knocking our website offline. We do not know who is behind those attacks or what their motive is. There is no obvious financial gain in targeting our publication. When a news site is repeatedly taken down, it is fair to wonder whether its reporting has made it a target--and whether that means we are doing something right.

For us, the immediate cost is lost access to our readers. For a hospital, a city or a utility, the consequences could be much more serious.

Three days without normal services

Governments are urging citizens to prepare for disruptions. The United Kingdom and Canada recommend keeping essential supplies for at least 72 hours; the Netherlands and Poland offer similar three-day guidance, and the European Union has urged member states to work toward 72-hour household self-sufficiency.

These recommendations cover many kinds of emergencies. They do not prove officials are anticipating a specific cyberattack. But they raise a serious question: In a world where essential services depend on digital networks, could cyberattacks be among the disruptions families may need to endure?

What happens if a hack leaves a bank, hospital, city or utility unable to operate normally for days--or longer? How do families pay for essentials if payment networks are unavailable? How do patients get care when hospital systems are compromised? How does a city coordinate emergency services if its communications networks fail? What happens when a water provider cannot trust the systems it uses to monitor its facilities?

An attack that interrupts power, water, payments or communications could create the kind of emergency those supplies are meant to help people weather. It is reasonable to prepare. It is also reasonable to ask whether our critical systems are secure enough that families must plan for basic services to disappear.

A safer internet--or a more controlled one?

If a major cyberattack causes widespread disruption, the public will demand protection. Governments will promise security. Technology companies will offer systems that can verify users, detect suspicious behavior and shut down threats before they spread.

Some changes could help. Critical infrastructure may be separated from public networks. Banks and government systems may require stronger authentication. Websites may rely on AI tools to identify attacks in real time. More services could move to identity-verified accounts, while anonymous access becomes harder to find.

But imagine how that shift could feel in daily life. You try to open a site and are asked to verify your identity. A biometric scan becomes the quickest way through the login screen. Your AI assistant handles banking and shopping, but its actions are monitored and restricted by financial institutions. A security system flags your behavior as unusual, and an automated decision blocks your access until you prove who you are.

The internet might still look familiar on the surface. The same apps, websites and services may be there. Yet the freedom to browse, speak, transact or create an account without being identified could steadily disappear. Measures introduced as emergency safeguards could become routine. What begins as protection against hackers could turn into a system where access depends on verified identity and every action leaves a record.

That is speculation, not a forecast. A cyber crisis does not have to lead to a surveillance internet. But tighter controls could be built one "temporary" safeguard at a time, especially if people are frightened and the tradeoff is presented as safety versus risk.

The AI contradiction

There is another unsettling tension in the AI boom. Anthropic's recent public filing warns investors that advanced AI could pose "catastrophic or existential risks to humanity," while the company prepares for a potential public offering that could raise enormous sums to expand its business.

That warning does not prove catastrophe is inevitable. And Anthropic's reported $80.7 billion loss in the first half of 2026 was largely driven by a non-cash accounting charge, not $80 billion in operating expenses. But the contradiction remains: AI developers warn that the technology could produce consequences they cannot control even as they race to build more powerful systems and attract more investment.

Anthropic says its safety work is designed to reduce those risks, while acknowledging success is not guaranteed. Investors and the public should ask a basic question: If the companies building advanced AI cannot assure us that the risks are under control, why are we so eager to finance a race that may make them harder to contain?

What will we trade for security?

AI-assisted hacking could make attacks faster and more damaging. Financial platforms have been hit. Water systems have been targeted. Supermarket refrigeration has been disrupted. PNW has felt firsthand what it means to be knocked offline.

We need stronger defenses, reliable backups and sensible emergency preparation. But we should be clear about what we are defending: not just our infrastructure, but our ability to live without constant digital supervision.

The internet of 2027 may still connect us to the same services. The difference could be that every login is checked, every transaction is monitored and every user is expected to prove who they are. Cyberattacks may bring the internet to its knees. The decisions made in response could determine whether it rises again as an open network--or as a tightly controlled system where everyone is identified, tracked and watched.
